ABSTRACT

This is a protocol for a Cochrane Review (Intervention). The objectives are as follows:

To assess the effects of pharmacological, behaviour change, and organisational interventions compared to comparator intervention in preventing diabetes among people with mental illness in LMICs.

BACKGROUND

Mental disorders have been identified as substantial and increasing sources of global disease burden. They are now one of the leading causes of disability worldwide, accounting for almost a quarter of all years lived with a disability (Murray 2012; Vos 2012) and significantly increased mortality (Correll 2017; Lawrence 2010; Mitchell 2013; Scott 2009). Studies have repeatedly reported a 10 to 20 years mortality gap for people with mental illness, and, despite an overall improvement in life expectancy in recent years, the absolute mortality gap between people with mental illness and those without, is actually widening (Chesney 2014; Hayes 2017; Olfson 2015; Saha 2007). Studies from low- and middle-income

countries (LMIC) show a similar pattern of increased mortality but with an even greater reduction in life expectancy than in high-income countries (Dube 1984; Fekadu 2015; Kurihara 2011; Mogga 2006). However, only 0.5 to 2% of the health budget is allocated for the prevention and treatment of mental disorders in LMICs (Stubbs 2017), and mental illness remains a major health challenge in these countries (Rathod 2017).

A considerable proportion of the increased morbidity and mortality experienced by people with mental disorders is driven, not by the mental illness, but by comorbid physical illnesses (Hayes 2017). The vast majority of deaths (around 80%) are due to preventable physical illnesses, most commonly cardiovascular,

metabolic and respiratory diseases, and infections (Correll 2017; Crump 2013; Laursen 2011). Mental and physical disorders have a complex and bidirectional relationship. A higher prevalence of comorbid physical health conditions (e.g. diabetes and cardiovascular disease) and poorer management of these illnesses contribute to health inequalities in people with mental illness (Vancampfort 2016a; Ward 2015). People with severe mental illness (SMI) (e.g. schizophrenia and bipolar disorder) have a particularly high risk of developing conditions such as diabetes and cardiovascular disease for reasons associated with the underlying mental disorder, health risk behaviours (such as physical inactivity, smoking, poor diet) (Vancampfort 2017) and treatments that increase cardiometabolic risks and mortality (Liu 2017). Conversely, common mental disorders (e.g. depression and anxiety) are more common in people with these physical health conditions (Das-Munshi 2007).

Globally, noncommunicable chronic diseases, such as diabetes, are a major cause of morbidity and mortality (contributing to 60% of all deaths) (Miranda 2008), including in LMICs (Lopez 2006). Diabetes is strongly associated with mental illness (Vancampfort 2015a); for example, around 13% of people with SMI (Ward 2015) and 9% of people with major depressive disorder (Vancampfort 2015b) have diabetes compared to 8.5% of the general population globally (WHO 2016) and 6% in the UK (Reilly 2015). Several interventions have been found to be effective for prevention of type 2 diabetes in the general population (Merlotti 2014; White 2016). Prevention of diabetes in people with mental illness is also clearly important. However, due to a complex combination of psychological, social, and financial barriers, generic interventions to prevent diabetes may not be suitable for people with mental disorders (Chwastiak 2015). Some of the additional barriers faced by people with mental illness, not addressed by generic interventions, include social stigma, poor access to medical care (Bradford 2008), fragmentation and lack of coordination between medical and psychiatric treatment in the healthcare systems of many countries (Druss 2010), and 'diagnostic overshadowing', where physical health problems are overlooked by health professional in the presence of mental illness (Liu 2017). These difficulties compound the challenges of managing side effects of psychotropic medication and the higher prevalence of health risk behaviours.

To date, only a limited number of systematic reviews have investigated the effectiveness of interventions to prevent diabetes for people with mental illness (McGinty 2016; Taylor 2017). These reviews have reported that diabetes can be prevented or its onset delayed, but included studies were mostly from high-income countries.

A comprehensive review by McGinty and others included 33 studies of interventions for diabetes mellitus in people with SMI. It found no high-quality evidence for the effectiveness of any interventions; the best available evidence suggested a potential beneficial effect of metformin on glycated haemoglobin (HbA1c) in this

group (McGinty 2016).

Currently, little is known about the effectiveness of interventions for preventing diabetes among patients with mental illness in LMICs. The review by Taylor and colleagues, which focused on people with SMI, included 54 randomised controlled trials (RCTs) among which only a few were from LMICs (Brazil, India, China, Iran, Venezuela). However, there was no subgroup analysis for LMICs and the review excluded people with other forms of mental disorder. Although the review found some evidence for the effectiveness of pharmacological and nonpharmacological interventions for improving glycaemic measurements for patients with SMI (Taylor 2017), we cannot assume that interventions designed for high-income countries will be suitable or effective for LMICs.

Other similar reviews have investigated the effect of pharmacological (Maayan 2010; Mizuno 2014), behavioural (Bruins 2014; Caemmerer 2012; Fernández-San-Martín 2014), or both pharmacological and behavioural interventions (Faulkner 2007) on glycaemic measurements in people with SMI. They have also reported that these interventions may be effective, but again have focused only on people with SMI or those taking antipsychotic medication, and identified very few studies in LMICs. Moreover, these studies considered glycaemic effects as a secondary outcome. A review of the effectiveness of interventions designed to prevent diabetes in people with any mental disorder, focused on LMICs, is therefore needed to inform practice and future research for this population.

Description of the condition

Diabetes is a serious lifelong condition, which is a major health challenge, with increasing prevalence worldwide showing a particularly sharp rise in LMICs (Stubbs 2016).

Ninety percent of people with diabetes have type 2 diabetes (T2DM), a metabolic disorder resulting from a defect in insulin secretion, insulin action, or both, with disturbances of carbohydrates, fat, and protein metabolism. Insulin deficiency leads to hyperglycaemia (elevated levels of plasma glucose). Eventually this may lead to microvascular retinopathy (disease of the retina which results in impairment or loss of vision), nephropathy (an abnormal state of the kidney especially one associated with or secondary to some other pathological process), neuropathy (an abnormal and usually degenerative state of the nervous system or nerves) and macrovascular (cardiovascular) complications.

The 'epidemic' of diabetes over recent decades has been attributed to changes in demographics and lifestyle globally (increased life expectancy, sedentary behaviours, and consumption of high fat and carbohydrate diets) (Miranda 2008), with LMIC populations experiencing especially rapid changes, with which health policy and services have failed to keep pace (Popkin 2002). The risk of developing diabetes increases with age, obesity, lack of physical activity, dyslipidaemia (abnormal amount of lipids in the blood),

and hypertension (ADA 2017), all of which have been adversely affected by these changes.

There is evidence that mental illness and diabetes comorbidity is very common. A recent systematic review and comparative meta-analysis by Vancampfort and colleagues established that people with SMI were significantly 1.85 times (95% CI: 1.45 to 2.37) more likely to have T2DM than matched controls (Vancampfort 2016a). Other systematic reviews and meta-analyses have demonstrated that all SMI diagnosis subgroups, such as schizophrenia and bipolar disorder, have a higher risk of developing T2DM than the general population (Pillinger 2017; Stubbs 2015; Vancampfort 2013; Vancampfort 2015b). There is also good evidence of an association between diabetes and common mental disorders (Das-Munshi 2007; Moulton 2015; Vancampfort 2016b). Patients with diabetes have a two- to three-fold increased prevalence of depressive disorders (Anderson 2001; Ali 2006) and anxiety (Grigsby 2002), although this relationship is likely to be bidirectional (Golden 2008).

Description of the intervention

There are different types of interventions that target the prevention of diabetes; pharmacological, behaviour change and organisational interventions. Pharmacological interventions aimed at prevention of diabetes in people with mental disorder include diabetes medication, weight loss medication, combination of diabetes and weight loss medication, diabetes preventive medication and antipsychotic switching. Behaviour change interventions may target health risk behaviours, and include patient education programmes, psychological interventions (e.g. cognitive-behavioural therapy or counselling), behavioural approaches (e.g. motivational interviewing), self-monitoring (including telehealth, internet-based interventions, and other communication technologies) or multicomponent interventions (e.g. self-management programmes that combine education and behavioural approaches) (Taylor 2017). Organisational interventions may include interventions that aim to improve the delivery of care, such as educating health professionals, care planning, or collaborative models of care (Druss 2010). It may be that there are particular pharmacological, behavioural and lifestyle, or organisational interventions that would be more applicable to LMICs as the availability of pharmacological interventions, resources and organizational structures in LMICs are different from high-income countries. For instance, in LMICs some drugs may not be available yet, behavioural interventions might not be feasible due to lack of trained personnel or there may not be any collaborative models of care in the health system (Koyanagi 2017).

In addition, LMICs are not a homogenous group of countries; there may be variation as to what is available among LMICs. There may be an intervention that is available in some LMICs but not others. For instance, not all pharmacological interventions are available in every LMIC and there is variability in health care re-

sources and organizational structures (Mate 2013). Therefore, for this review we will include all pharmacological, behaviour change and organisational interventions, as it is difficult to define these a priori, and we do not want to risk excluding effective interventions. Moreover, trials may test interventions that are not currently available in order to justify their inclusion in subsequent national formularies.

How the intervention might work

Pharmacological interventions

There are several modes of action for medication in preventing diabetes. Diabetes medication helps regulate carbohydrate and fat metabolism, by increasing insulin sensitivity and reducing the amount of glucose produced and released by the liver. Weight loss medication or anti-obesity drugs usually act on the gastrointestinal tract by reducing absorption of dietary fat, stimulate energy expenditure and decrease fat storage, or decrease appetite. Diabetes combination medications allow patients to switch between treatments depending on clinical response. Switching to or adding an atypical antipsychotic associated with fewer metabolic side effects is hypothesised to alleviate weight gain and metabolic abnormalities caused by commonly used antipsychotics such as olanzapine and clozapine. Other medications may work by enhancing lipid profile and metabolic function and regulating or increasing insulin sensitivity (Taylor 2017).

Behaviour change interventions

These target health risk behaviours using educational, psychological, and behavioural approaches, or combinations of these. For diabetes, there has been a particular focus on self-management interventions, influenced by several theories of health behaviour change, including social cognitive theory (Bandura 1986), the theory of reasoned action and planned behaviour (Ajzen 1991), self regulation theory (Leventhal 1984) and the transtheoretical model (Prochaska 1997). All of these theories identify concepts that predict health behaviour (and that may be targeted by behaviour change interventions), with a primary focus on beliefs, attitudes, and expectations. For example, a diabetes self-management intervention based on social cognitive theory (Bandura 1986) may seek to reduce carbohydrate intake by increasing diet-related self-efficacy. These behaviour change techniques are proposed to be the 'active ingredients' that explain how a self-management intervention might work (McBain 2016).

Organisational interventions

Organisational capacity building and training programmes increase the efficacy and communication skills of mental health professionals or health workers and health services to support prevention of diabetes for people with mental illness (Liu 2017).

Why it is important to do this review

Despite the high prevalence of comorbid mental illness and diabetes, there is a lack of research on development of evidence-based interventions for prevention of diabetes in people with mental disorders in LMICs. This systematic review will summarise the evidence for pharmacological, behaviour change, and organisational interventions that are targeted at the prevention of diabetes in people with mental disorders in LMICs.

OBJECTIVES

To assess the effects of pharmacological, behaviour change, and organisational interventions compared to comparator intervention in preventing diabetes among people with mental illness in LMICs.

METHODS

Criteria for considering studies for this review

Types of studies

We will include randomised controlled trials evaluating any interventions to prevent type 2 diabetes in people with any mental disorder in LMICs. LMICs will be defined according to the Development Assistance Committee (DAC) list of all countries and territories eligible to receive official development assistance (ODA) (DAC 2017).

Types of participants

We will include studies of adults aged 18 years and over, with any mental disorder and without diabetes, conducted in LMICs. Studies that do not explicitly screen for and exclude diabetes at baseline will not be included. Mental illness diagnosis should be established using WHO International Classification of Diseases (ICD) criteria for mental and behavioural disorders (ICD-10, F20-29 and F30-31, F 32.3, F33.3) (WHO 1992) and/or the Diagnostic and Statistical Manual of Mental Disorders (DSM) (DSM-III, APA 1980; DSM-III-R, APA 1987; DSM IV, APA 2000; DSM V, APA 2013) or measures based on these. We will define SMI as

schizophrenia or other psychotic disorders, bipolar disorder, and depression with psychotic features. Common mental disorders will include depression, generalised anxiety disorder (GAD), panic disorder, phobias, social anxiety disorder, obsessive-compulsive disorder (OCD), and post-traumatic stress disorder (PTSD) (NICE 2011). Other mental disorders such as personality disorder and somatoform disorders will also be included in this review.

Where study populations are mixed (i.e. including people with and without mental disorder), studies will be included only if people with mental disorders constitute the predominant population, or if separate outcome data are provided for them.

Studies involving children or people who already have diabetes, or studies not conducted in LMICs will not be included in this review.

To be consistent with changes in the classification of, and diagnostic criteria for diabetes mellitus over the years, studies should use (and explicitly state) established standard criteria for the diagnosis of T2DM, valid at the time of the trial commencing (e.g. ADA 1999; ADA 2008; ADA 2017; WHO 1999; WHO 2006).

Types of interventions

Experimental intervention

The review will include any pharmacological, behaviour change (targeting health risk behaviours), or organisational intervention that targets the prevention of diabetes in people with any mental disorder in LMICs.

Pharmacological interventions will include any medication-related interventions, for instance: diabetes medication (e.g. metformin, pioglitazone); weight loss medication (e.g. amantadine, orlistat, sibutramine); combination of weight loss and diabetes drugs (e.g. amantadine with metformin and zonisamide; metformin with amantadine and zonisamide; metformin with sibutramine); antipsychotic switching (e.g. changing to aripiprazole, quetiapine, or ziprasidone); or use of other medications purported to prevent diabetes. These are examples of potential drugs rather than a definitive list.

Behaviour change interventions commonly target health risk behaviours (for example, improving physical activity or diet). This review will include any behaviour change intervention targeting at prevention or delaying the onset of diabetes, for example: patient education programmes, psychological interventions (e.g. cognitive behavioural therapy or counselling), behavioural approaches (e.g. motivational interviewing), self-monitoring (including telehealth, internet-based interventions and other communication technologies) and, multicomponent interventions (for example, self-management programmes that combine education and behavioural approaches).

Organisational interventions included will be those that aim to improve the delivery of care, such as educating health professionals,

care planning, or collaborative models of care. Examples, include relevant training of any health professionals working with people with mental illness, nonspecific health worker interventions, community mental health teams, mass media-delivered interventions, family interventions, physical health care monitoring, and statutory mental health services intervention.

Comparator intervention

For pharmacological interventions, comparator interventions will include no treatment (including trials employing wait-list conditions), treatment as usual, placebo drugs or an alternative type of medication for diabetes prevention.

For behaviour change and organisational interventions we will include the following comparators: usual care or treatment, attention or other psychological placebo control, or any alternative behaviour change or organisational intervention (as described above under experimental interventions).

Types of outcome measures

Primary outcomes

Our primary outcome for this review is prevention of diabetes. A clinical diagnosis of diabetes may be confirmed in the presence of symptoms by various parameters such as HbA1c, fasting blood sugar, random blood sugar or, in unclear cases, 2-hour plasma glucose following an oral glucose tolerance test (OGTT). We will accept diagnoses made using any of these parameters using cut-offs consistent with those current at the time of the study, as described in national and international guidance such as WHO (e.g. WHO 2006), National Institute of Health and Care Excellence (NICE) (e.g. NICE 2015), Diabetes UK (e.g. Diabetes UK 2018), American Diabetes Association (e.g. ADA 2017). Current cut-offs are as follows: HbA1c ≥ 48 mmol/mol, a fasting blood glucose ≥ 7 mmol/L or a random blood glucose ≥ 11.1 mmol/L; and for OGTT 2-hour glucose ≥ 11.1 mmol/L (ADA 2017). Conversion to prediabetes will not be included.

As the adverse primary outcome, we will report drop-out: the number of participants who drop out of treatment for any reason.

Secondary outcomes

- Body Mass Index (BMI)
- Waist circumference
- Blood pressure
- Cholesterol
- Depression and anxiety measured by a validated scale, e.g. Patient Health Questionnaire (PHQ 9) (Kroenke 2001), Generalised Anxiety Disorder assessment (GAD-7) (Spitzer 2006)

- Health related quality of life (evaluated with a validated generic or disease-specific instrument (Wee 2006), like: 36-Item Short Form Health Survey (SF-36) (McHorney 1993) or other validated scale). We will consider language- and culture-adapted instruments, where these are available

- All-cause mortality, defined as death from any cause

Search methods for identification of studies

Cochrane Common Mental Disorders Controlled Trials Register (CCMDCTR)

The Cochrane Common Mental Disorders Group (CCMD) maintains a specialised register of randomised controlled trials, the CCMDCTR. This register contains over 40,000 reference records (reports of RCTs) for depression, anxiety, bipolar disorder, eating disorders, self-harm, and other mental disorders within the scope of this group. The CCMDCTR is, in part, a studies-based register, with > 50% of reference records tagged to approximately 12,500 individually PICO-coded study records. Reports of trials for inclusion in the register are collated from (weekly) generic searches of MEDLINE, Embase, and PsycINFO; quarterly searches of the Cochrane Central Register of Controlled Trials (CENTRAL); and review-specific searches of additional databases. Reports of trials are also sourced from international trials registries, drug company websites, and handsearching of key journals, conference proceedings, and other (non-Cochrane) systematic reviews and meta-analyses.

Details of CCMD's core search strategies (used to identify RCTs) can be found on the Group's website (Cochrane 2014). In 2016, the Group's Specialised Register (CCMDCTR) fell out of date with the Editorial Group's move from Bristol to York.

Electronic searches

The CCMD Group's Information Specialist (JW) will cross-search the CCMDCTR (studies and references register) using the following search terms to find reports of randomised controlled trials (RCTs): (*diabet** or (*(glucose or glycaemic or glycaemic) near3 control**)) [all fields]

In addition, JW will search the following electronic databases with a comprehensive search strategy, derived from terms related to diabetes, mental disorders, LMICs, RCTs and systematic reviews. Search strategies will be informed by the review of Taylor and colleagues (Taylor 2017), the Cochrane highly-sensitive search strategies for identifying randomised controlled trials (Lefebvre 2011), and the AUHE Information Specialist LMIC geographic strategies (AUHE 2018). The searches will not be limited by date, language, or publication status. In keeping with the Cochrane MECIR conduct standards, we will run a search for retractions and errata once the included studies have been selected.

An example of the MEDLINE strategy is provided in [Appendix 1](#).

The search strategy will be translated across to the other databases listed below, using relevant subject headings and search syntax appropriate to each resource.

- CINAHL (EBSCO) (1981 to present);
- Cochrane Central Register of Controlled Trials (current issue);
- Cochrane Database of Systematic Reviews (current issue);
- Embase Classic + Embase (Ovid) (1947 to present);
- Global Health (Ovid) (1910 to present);
- Indian Medlars (indmed.nic.in/) (all available years);
- LILACs (lilacs.bvsalud.org/en/) (all available years);
- Ovid MEDLINE(R) (1946 to present), MEDLINE In-Process & Other Non-Indexed Citations, MEDLINE Epub Ahead of Print;
- PsycINFO (Ovid) (1806 to present);
- PubMed (NLM) (1946 to present);
- PakMedNet (www.pakmedinet.com/) (all available years).

Searching other resources

Some grey literature will already have been identified in searches of the electronic databases listed above (e.g. conference abstracts in EMBASE, dissertations in PsycINFO, handsearch results in Cochrane CENTRAL). However, further searching will be undertaken as listed below.

Grey literature

We will identify grey literature from:

- conference Proceedings Citation Index - Science (Clarivate Analytics Web of Science) (1990 - present);
- we will search ProQuest Dissertations & Theses Global.

Unpublished studies

We will search the following international trial registries to identify ongoing or unpublished studies (all available years):

- ISRCTN registry (Springer Nature);
- ClinicalTrials.gov (U.S. NIH);
- International Clinical Trials Registry Platform (WHO).

Reference lists

We will check the reference lists of all included studies and relevant systematic reviews to identify additional studies.

Correspondence

We will contact trial authors and subject experts to identify any additional work which is unpublished or to request additional trial data.

Data collection and analysis

Selection of studies

We will upload citations and available abstracts of the search results into Covidence ([Covidence 2017](#)) and screen for potential eligibility in two stages. Covidence is a primary screening and data extraction software, which helps to streamline the production of standard intervention reviews. The first stage will involve screening titles and abstracts to exclude studies that do not meet the inclusion criteria, carried out independently by three pairs of reviewers (MPM and EJP; NT and JT; RA and ZA). Discrepancies will be resolved through discussion, and, where an agreement cannot be reached, a third reviewer (NS) will be consulted. In the second stage, we will retrieve the full text of potentially eligible studies and independently assess them for eligibility, again by three pairs of reviewers (MPM and EJP; NT and JT; RA and ZA). We will seek any missing data that could help to assess eligibility by contacting the corresponding authors. We will present a PRISMA flow diagram to show the process of trial selection ([Liberati 2009](#)). For studies excluded during this stage, a reason for exclusion will be recorded. Discrepancies will be resolved by consulting a third reviewer (NS), who will independently assess the study under consideration. For included studies, we will link multiple reports from the same study.

Data extraction and management

For trials that fulfil our inclusion criteria, three pairs of review authors (MPM and EJP; NT and JT; RA and ZA) will extract data. For each study, one reviewer will complete a tailored and pre-piloted data collection form based on the Cochrane Consumers and Communication Group's Data Extraction Template for Cochrane Reviews (<http://cccrg.cochrane.org/author-resources>), which will then be checked independently by a second reviewer. We will resolve any discrepancies by discussion, or, if required, we will consult a third review author (NS).

To provide information for assessment of study quality and for evidence synthesis, the following data will be extracted:

1. Study population (including participant inclusion and exclusion criteria);
2. Country;
3. Setting (primary care, community, secondary care, mental health care);
4. Study design;
5. Number of intervention groups;
6. Intervention:
 - i) For pharmacological interventions: class of drug, dose, frequency, and duration;
 - ii) For behavior change and organisational interventions: description of the intervention (including process, target group, e.g. patients or healthcare professionals, and presence of other cointerventions), theory (informing intervention design), target (including strategies, applications, and components), context of intervention (i.e. primary health facility), provider and mode of delivery (phone, face-to-face, group, online), intensity (length,

frequency, and number of contacts), duration (period of time over which contacts delivered), details about group leader (demographics, training, professional status, etc.);

iii) Behaviour change techniques. We will categorise interventions and identify behaviour change techniques using the 'template for intervention description and replication' (TIDieR) checklist (Hoffmann 2014; Hoffmann 2017).

7. Comparison intervention(s).

We will note in the 'Characteristics of included studies' table if the study authors did not report outcome data in a usable way. Where included trials reported outcome data in insufficient detail to include in a meta-analysis, for instance, reporting means without confidence intervals (CIs) or standard deviations (SDs), we will contact the study authors to request more information.

Assessment of risk of bias in included studies

We will assess the methodological quality of included randomised trials using the Cochrane 'Risk of bias' tool (Higgins 2011a). The following items will be assessed:

- Sequence generation (i.e. if allocation sequence adequately generated);
- Allocation sequence concealment (i.e. if allocation adequately concealed);
- Blinding (i.e. if knowledge of the allocated interventions adequately prevented during the study);
- Incomplete outcome data (i.e. if incomplete outcome data adequately addressed);
- Selective outcome reporting (i.e. whether reports of the study are free of suggestion of selective outcome reporting);
- Other potential sources of bias (i.e. whether the study is apparently free of other problems that could lead to a high risk of bias e.g. baseline imbalances, evidence of carry-over in cross-over trials, comparability of groups in cluster trials).

We will judge each potential source of bias as high, low or unclear and provide a supporting quotation from the study report together with a justification for our judgment in the 'Risk of bias' table. We will summarise the risk of bias judgements across different studies for each of the domains listed. Three pairs of review authors (MPM and EJP; NT and JT; RA and ZA) will independently rate the certainty of evidence for each outcome. Differences in assessment will be resolved by discussion or consultation with a third researcher (NS). Allocation concealment will be used as a marker of trial quality for the purposes of undertaking sensitivity analyses.

Measures of treatment effect

For continuous data, we will calculate the mean difference (MD) with 95% confidence interval (CI). Where trials report the same outcome using different outcome measures, we will use standardized mean difference (SMD). For binary outcomes, a standard es-

timation of the risk ratio (RR) with a 95% CI will be calculated using Review Manager (Review Manager 2014). In case an eligible study describes its findings using another effect measure, we will contact the study authors to obtain data and if we do not receive the necessary information from trial authors, we will impute these values.

Unit of analysis issues

We will take into account the level at which randomisation occurred, with respect to cross-over trials, cluster RCTs, and multiple observations for the same outcome.

We will attempt to reanalyse cluster-RCTs that have not appropriately adjusted for potential clustering of participants within clusters in their analyses by inflating the variance of the intervention effects by the design effect. We will obtain estimates of the intracluster correlation coefficient (ICC) in order to estimate the design effect through contact with authors, or impute them by using either estimates from other included trials that report ICCs or external estimates from empirical research (e.g. Bell 2013).

In the case of multiple intervention groups, we will analyse each intervention group separately against the control group and the sample size for the control group will be divided proportionately across each intervention group. Where results are reported at multiple time points in the studies, we will analyse each outcome at predefined periods of follow-up in separate meta-analyses. We will group time points as follows: less than six months, and six months or more. We have selected these time points as representing time frames in which a difference in the likelihood of responding could be expected.

If more than one comparison from the same trial is eligible for inclusion in the same meta-analysis, we will either combine groups to create a single pairwise comparison or appropriately reduce the sample size so that the same participants do not contribute data to the meta-analysis more than once (i.e. splitting the 'shared' group into two or more groups), although we acknowledge this will not account for correlation arising from the same set of participants being in multiple comparisons (Higgins 2011a).

Dealing with missing data

We will carefully evaluate important numerical data such as screened and randomly assigned participants as well as intention-to-treat, and as-treated and per-protocol populations. We will investigate attrition rates (e.g. dropouts, losses to follow-up, withdrawals), and we will critically appraise issues concerning missing data.

Data will be analysed primarily using the intention-to-treat (ITT) principle. However, if the included studies do not provide enough detail to allow for an ITT analysis, and where included trials do not report means and SDs for outcomes, data will be requested from study authors. However, if we do not receive the necessary information from trial authors, we will impute these values (Higgins

2011a; Higgins 2011b). We will investigate the impact of imputation on meta-analyses by performing sensitivity analyses.

Assessment of heterogeneity

Clinical heterogeneity will be assessed through the description of the setting, baseline measures, and intervention approach used in each study. In the case of obvious clinical heterogeneity we will not pool the data and the studies will be described.

Statistical heterogeneity will be assessed using the Chi² test and the I² statistic. The Chi² test will be considered statistically significant if $P \leq 0.10$. If heterogeneity exists between studies ($I^2 \geq 50\%$) for the primary outcome, reasons for the heterogeneity will be explored. Our exploration will follow the Cochrane Handbook guidance (Deeks 2011), which suggests the following guidance for interpretation of the I² statistic:

- 0 to 40%: might not be important
- 30% to 60%: may represent moderate heterogeneity
- 50% to 90%: may represent substantial heterogeneity
- 75% to 100%: considerable heterogeneity

We will take into account (i) magnitude and direction of effects and (ii) strength of evidence for heterogeneity (e.g. the P value from the chi²-squared test, or a confidence interval (CI) for I²) when interpreting the I² statistic.

Assessment of reporting biases

If more than 10 studies that investigate a particular outcome are identified for inclusion in this review, funnel plots will be used to assess publication biases. Quantitative analysis of publication bias such as the Egger test will also be conducted.

Data synthesis

Data from individual trials will be combined by meta-analysis if the interventions, outcomes, and patient groups are sufficiently similar (determined by expert consensus).

Data will not be pooled for meta-analysis if we detect a high degree of heterogeneity ($I^2 > 75\%$). Where data are pooled, a random-effects model will be used as a consideration of the heterogeneity of populations.

Subgroup analysis and investigation of heterogeneity

We plan to carry out the following subgroup analyses, based on characteristics of the population or intervention that might be expected to influence the primary outcome:

- Age (65 years and over) and gender, which may influence risk of diabetes;
- Type of mental disorder (SMI versus other mental disorder; people with SMI have additional risk factors for diabetes e.g. side effects of antipsychotic medication);

- Prospective identification of diabetes using a robust approach to diagnosis e.g. HbA1c or fasting blood sugar, versus studies using retrospective records, random blood glucose testing, or both;

- Intervention duration (less than three months versus three months or more; intensity of the intervention may influence outcomes);

- Duration of follow-up (less than three months versus three months or more; this is likely to influence detection of outcomes).

Sensitivity analysis

For outcomes where two or more studies are available to include in a meta-analysis, we will perform sensitivity analyses to explore the influence of the following factors (where applicable) on effect sizes:

- effect of risk of bias: studies that have not used allocation concealment will be excluded;

- effect of large trials: large trials will be excluded to establish the extent to which they dominate the results;

- effect of data imputation: trials where missing data have been imputed will be excluded.

We have restricted the planned sensitivity analyses to these as they are likely to be the most relevant in influencing findings.

'Summary of findings' table

We will prepare 'Summary of findings' tables to summarise key findings of this review. We will report the outcomes (including adverse outcomes) and present standardised effect size estimates and 95% CIs, using the GRADE approach to assess the overall quality of the evidence supporting each outcome. GRADE criteria take into account issues related not only to internal validity (risk of bias, inconsistency, imprecision, publication bias) but also to external validity, such as directness of results. We will use GRADE-proGDT to create our 'Summary of findings' tables (GRADEpro 2015), and follow standard methods as described in the *Cochrane Handbook for Systematic Reviews of Interventions* to prepare our 'Summary of findings' table (Schünemann 2017). For each of our main comparisons, the following outcomes (measured up to 12 months) will be included:

- Diabetes diagnosis determined by HbA1c or fasting blood glucose or measured via other diagnosis method current at the time the study was conducted);

- Drop-out;
- BMI;
- Health-related quality of life;
- Mortality.

The definitive list of comparisons to be included in the 'Summary of findings' tables will be agreed with clinicians once the categories

of interventions are known, guided by clinical relevance. This is because the range of interventions to be included is broad, and at this stage, we cannot know which categories of intervention will be identified by the review.

'Summary of findings' tables will be created after we have entered data into RevMan (Review Manager 2014), written up our results, and conducted the 'Risk of bias' assessment. However, the 'Summary of findings' table will be created before writing our discussion, abstract, and conclusions, to allow the opportunity to consider the impact of the risk of bias in the studies contributing to each outcome upon the mean treatment effect and our confidence in these findings.
